THE WAVE NATURE OF LIGHT

☞ Interference of Water Waves
(P.462-469)

Interference

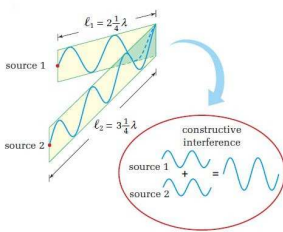

*When two waves cross paths and become superimposed, they interact in different ways. The interaction between waves in the same medium is called **interference**.*

December 1, 2012 4U4 - Interference of Water Waves 1

Interference

*If the crest of one wave coincides with the crest of the other, then the waves are in phase and combine to create a resultant wave with an amplitude that is greater than the amplitude of either individual wave. This phenomenon is called **constructive interference** and the point where the constructive interference occurs is referred to as an **anti-node**.*

December 1, 2012 4U4 - Interference of Water Waves 2

Interference

For two waves that differ in phase by $\frac{1}{2}\lambda$ (or 180°), the crest of one wave coincides with the trough of the other wave. The two waves combine and create a resultant wave with an amplitude that is smaller than either of the individual waves. This phenomenon is called **destructive interference** and the point where the destructive interference occurs is referred to as a **node**.

December 1, 2012 4U4 - Interference of Water Waves 3

Interference

NOTE!
In order for interference to occur, the waves must have the same frequency and a fixed phase difference. Waves that meet this condition are said to be **coherent**.

December 1, 2012 4U4 - Interference of Water Waves 4

Interference

INTERFERENCE

- ❖ phenomenon that occurs when two waves in the same medium interact
- ❖ waves must be coherent (same frequency and a fixed phase difference)
- ❖ two types:
 - ① constructive – waves have displacements in the same direction
 - ② destructive – waves have displacements in opposite directions

December 1, 2012 4U4 - Interference of Water Waves 5

Two-Point Interference

In the diagram below, the two points sources are coherent (i.e. same frequency and phase) and have equal amplitudes. Successive wave fronts travel out from the two sources and interfere with each other, producing a symmetrical line pattern of constructive and destructive interference.

December 1, 2012 4U4 - Interference of Water Waves 6

Two-Point Interference

The interference pattern includes lines of maximum displacement (**anti-nodal lines**), caused by constructive interference, separated by lines of zero displacement (**nodal lines**), caused by destructive interference.

December 1, 2012 4U4 - Interference of Water Waves 7

Two-Point Interference

PRACTICE

1. What happens to the pattern when the frequency increases?
 - the nodal (and anti-nodal) lines come closer together
 - the number of nodal (and anti-nodal) lines increases
 - the symmetry of the pattern remains constant

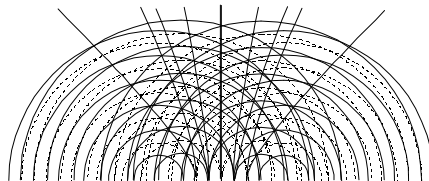

December 1, 2012 4U4 - Interference of Water Waves 8

Two-Point Interference

PRACTICE

2. What happens when the distance between the sources increases?

- the nodal (and anti-nodal) lines come closer together
- the number of nodal (and anti-nodal) lines increases
- the symmetry of the pattern remains constant

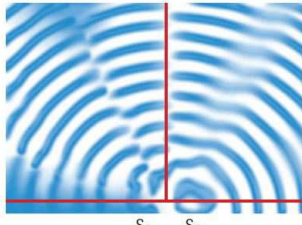

December 1, 2012 4U4 - Interference of Water Waves 9

Two-Point Interference

PRACTICE

3. What happens when the relative phase of the two sources changes.

the pattern shifts, but the number of nodal lines stays the same

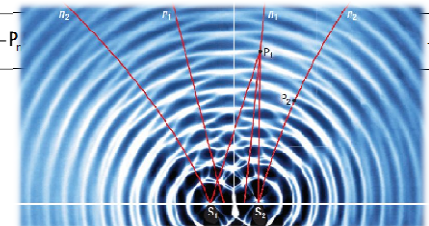

December 1, 2012 4U4 - Interference of Water Waves 10

Two-Point Interference – The Mathematics

NOTE!

You can measure wavelength using the interference pattern produced by two point sources and develop some mathematical relationships for studying the interference of other waves.

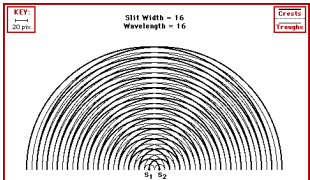

$$r_2 - r_1 = n\lambda = \left(\frac{X_n}{L} \right)$$
